# Collaborative Filtering for Movie Recommendation

**Comparing Classical and Neural Algorithms** 

Aditya Srivastava Harsh Gupta Akimun Jannat Alvina Niharika Narasimhiah Govinda Given a large number of movies, how do you make individually targeted recommendations for users to watch?

### **Motivation**

- Reduce decision making complexity with increasing options
- Drive user engagement and improve customer satisfaction
- Provide an edge over competitors

### **Movielens-100k Dataset**

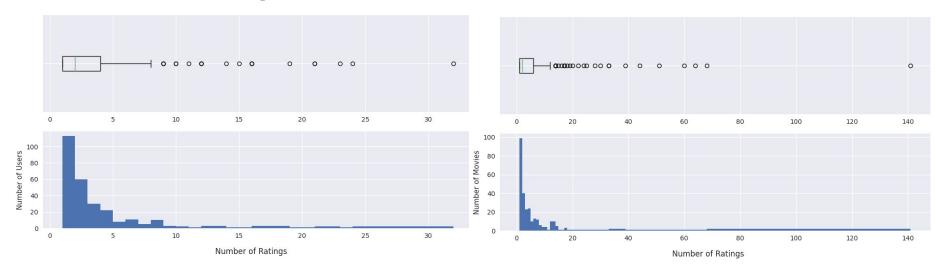

- Some numbers;
  - 100,000 movie ratings
  - 943 unique users
  - 1682 unique movies
- Extensively peer-reviewed
- Popular recommendation benchmark

# **Data Preprocessing**

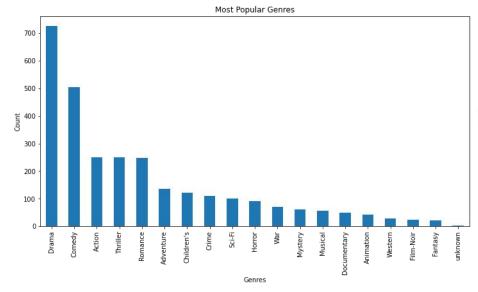

- Converted explicit ratings (1 to 5) to implicit (1 if rated, 0 if unrated)
- Min-Max scaled numerical features to [0, 1]
- One-Hot encoded categorical features
- Three types of model inputs generated
  - i. Training:
    - (user\_id, item\_id, rating)
    - (user id, pos item id, neg item id)
  - ii. Testing/Evaluation:
    - (user\_id, pos\_item\_id, [neg\_item\_id<sub>1</sub>, neg\_item\_id<sub>2</sub>, ... neg\_item\_id<sub>100</sub>])
- Negative features sampled randomly

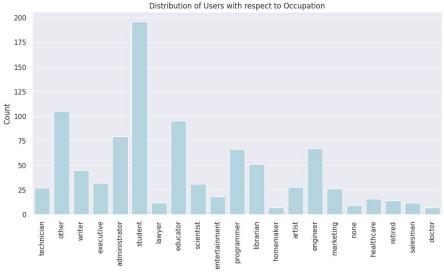

# **Data Analyses**

- Majority of users rate only a few movies
- Indicates a significant subset of highly active users
- Two distinct groups: casual raters and avid movie watchers
- Avid users contribute extensive ratings for hundreds of films

- Prevalence of movies with low ratings
- Dataset may feature numerous niche films
- Users tend to rate movies they are familiar with, overlooking lesser-known films

- Drama emerges as the most popular genre
- Followed by Comedy and Action in terms of frequency

- Students exhibit the highest inclination for rating movies
- Students consume more media, potentially leading to increased movie ratings
- Homemakers and doctors are less common in the dataset, as highlighted by the figure

#### **Correlation analysis:**

#### Genre and Gender Correlation

- Women show a preference for Romance movies, while men lean towards Sci-Fi

#### Inter-Genre Relationships

- Certain genres frequently co-occur, e.g., Animation with Children's and Musical, and Mystery with Thriller

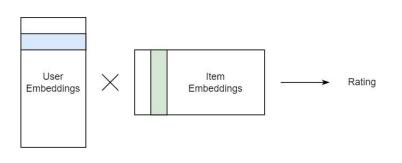

#### Gender and Occupation Bias

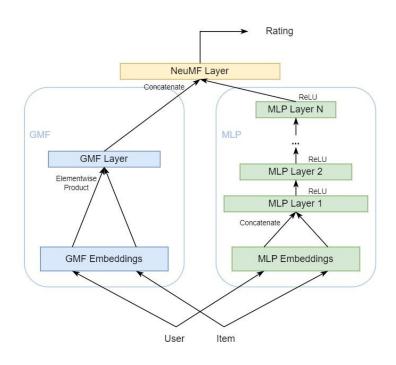

- Strong correlations suggest potential biases, with male users associated more with technical professions and female users linked to healthcare and homemaking occupations

# Method

### **Models**

Matrix Factorization (MF) Neural Co

**Neural Collaborative Filtering (NCF)** 

# **Objective Functions**

Three different loss functions:

### Root Mean Squared Error (RMSE)

Minimize difference between predicted rating and actual rating

#### 2. Binary Cross-Entropy (BCE)

• Minimize entropy of predicted distribution vs. actual distribution

### 3. Bayesian Personalized Ranking (BPR)

 Maximize the difference in predicted ratings of positive items and negative items

### **Evaluation Metrics**

Two different evaluation metrics:

### Hit Ratio (HR@K)

• Probability that a positive item's predicted rating falls within the top K ratings in a set where every other item is negative

#### 2. Normalized Discounted Cumulative Gain (NDCG@K)

 Same as HR however, there is higher penalization for ranking lower among the top K ratings

# **Experimental Setting**

- Experiments with combinations of models and objectives
- Model hyperparameters were adopted as given in source material
- Optimizers used:
  - Stochastic Gradient Descent (SGD) for RMSE and BPR
  - Adam for BCE
- Optimizer hyperparameters were grid searched
- NCF's GMF and MLP submodules were pretrained before NCF finetuning

### Results

		HR		NDCG			
	@1	@5	@10	@1	@5	@10	
MF-RMSE	0.31	0.65	0.80	0.31	0.49	0.54	
NCF-BCE	0.23	0.62	0.77	0.30	0.47	0.52	
MF-BPR	0.34	0.73	0.87	0.34	0.55	0.59	
NCF-BPR	0.38	0.38	0.38	0.38	0.38	0.38	

### **Comparing loss functions:**

- RMSE and BCE models shows similar performance
- Both RMSE and BCE models are outperformed by BPR

### **Comparing models:**

- Classical MF yields better results than NCF for almost every metric and with every loss function
- NCF-BPR may have better precision

### **Overall best: Matrix factorization model with BPR loss**

## **Results**

		HR		NDCG			
	@1	@5	@10	@1	@5	@10	
MF-RMSE	0.31	0.65	0.80	0.31	0.49	0.54	
NCF-BCE	0.23	0.62	0.77	0.30	0.47	0.52	
MF-BPR	0.34	0.73	0.87	0.34	0.55	0.59	
NCF-BPR	0.38	0.38	0.38	0.38	0.38	0.38	

### **Conclusions**

- Surprisingly, classical algorithm > neural counterpart
- Choice of loss function plays a crucial role in model effectiveness
- Indicative of traditional ML techniques still being relevant and competitive
- Factors that may have influenced performance
  - Dataset size disparity
  - Skipped content-based features
  - Model complexity and optimization
    - Neural models are more sensitive to tuning on smaller datasets

# Challenges

- Dealing with data bias
- Complex data preprocessing
- Cold-start problem
- Discrepancies between reference papers
- Missing reference details in reference papers
- Lack of reference code

### **Future Work**

- Dataset expansion:
  - Test models on the MovieLens 1M dataset for broader evaluation
- Comprehensive grid search:
  - Extend grid search to optimize model parameters, not just optimizers
- Content-based feature integration:
  - Explore leveraging content-based features in the dataset
- Content-based and hybrid model exploration:
  - Investigate content-based and hybrid models for more comprehensive analyses

# Thank you!
